

# Data Mining

Practical Machine Learning Tools and Techniques

Slides for Chapter 2 of *Data Mining* by I. H. Witten and E. Frank

# Input: Concepts, instances, attributes

- Terminology
- What's a concept?
  - ♦ Classification, association, clustering, numeric prediction
- What's in an example?
  - ♦ Relations, flat files, recursion
- What's in an attribute?
  - ♦ Nominal, ordinal, interval, ratio
- Preparing the input
  - ♦ ARFF, attributes, missing values, getting to know data

# Terminology

- Components of the input:
  - ♦ Concepts: kinds of things that can be learned
    - Aim: intelligible and operational concept description
  - ♦ Instances: the individual, independent examples of a concept
    - Note: more complicated forms of input are possible
  - ♦ Attributes: measuring aspects of an instance
    - We will focus on nominal and numeric ones

# What's a concept?

- Styles of learning:
  - ♦ Classification learning:  
predicting a discrete class
  - ♦ Association learning:  
detecting associations between features
  - ♦ Clustering:  
grouping similar instances into clusters
  - ♦ Numeric prediction:  
predicting a numeric quantity
- Concept: thing to be learned
- Concept description:  
output of learning scheme

# Classification learning

- Example problems: weather data, contact lenses, irises, labor negotiations
- Classification learning is *supervised*
  - ♦ Scheme is provided with actual outcome
- Outcome is called the *class* of the example
- Measure success on fresh data for which class labels are known (*test data*)
- In practice success is often measured subjectively

# Association learning

- Can be applied if no class is specified and any kind of structure is considered “interesting”
- Difference to classification learning:
  - ♦ Can predict any attribute’s value, not just the class, and more than one attribute’s value at a time
  - ♦ Hence: far more association rules than classification rules
  - ♦ Thus: constraints are necessary
    - Minimum coverage and minimum accuracy

# Clustering

- Finding groups of items that are similar
- Clustering is *unsupervised*
  - ♦ The class of an example is not known
- Success often measured subjectively

|     | Sepal length | Sepal width | Petal length | Petal width | Type            |
|-----|--------------|-------------|--------------|-------------|-----------------|
| 1   | 5.1          | 3.5         | 1.4          | 0.2         | Iris setosa     |
| 2   | 4.9          | 3.0         | 1.4          | 0.2         | Iris setosa     |
| ... |              |             |              |             |                 |
| 51  | 7.0          | 3.2         | 4.7          | 1.4         | Iris versicolor |
| 52  | 6.4          | 3.2         | 4.5          | 1.5         | Iris versicolor |
| ... |              |             |              |             |                 |
| 101 | 6.3          | 3.3         | 6.0          | 2.5         | Iris virginica  |
| 102 | 5.8          | 2.7         | 5.1          | 1.9         | Iris virginica  |
| ... |              |             |              |             |                 |

# Numeric prediction

- Variant of classification learning where “class” is numeric (also called “regression”)
- Learning is supervised
  - ♦ Scheme is being provided with target value
- Measure success on test data

| Outlook  | Temperature | Humidity | Windy | Play- time |
|----------|-------------|----------|-------|------------|
| Sunny    | Hot         | High     | False | 5          |
| Sunny    | Hot         | High     | True  | 0          |
| Overcast | Hot         | High     | False | 55         |
| Rainy    | Mild        | Normal   | False | 40         |
| ...      | ...         | ...      | ...   | ...        |

# What's in an example?

- Instance: specific type of example
  - Thing to be classified, associated, or clustered
  - Individual, independent example of target concept
  - Characterized by a predetermined set of attributes
- Input to learning scheme: set of instances/dataset
  - Represented as a single relation/flat file
- Rather restricted form of input
  - No relationships between objects
- Most common form in practical data mining

# A family tree

# Family tree represented as a table

| Name   | Gender | Parent1 | parent2 |
|--------|--------|---------|---------|
| Peter  | Male   | ?       | ?       |
| Peggy  | Female | ?       | ?       |
| Steven | Male   | Peter   | Peggy   |
| Graham | Male   | Peter   | Peggy   |
| Pam    | Female | Peter   | Peggy   |
| Ian    | Male   | Grace   | Ray     |
| Pippa  | Female | Grace   | Ray     |
| Brian  | Male   | Grace   | Ray     |
| Anna   | Female | Pam     | Ian     |
| Nikki  | Female | Pam     | Ian     |

# The “sister-of” relation

| First person | Second person | Sister of? |
|--------------|---------------|------------|
| Peter        | Peggy         | No         |
| Peter        | Steven        | No         |
| ...          | ...           | ...        |
| Steven       | Peter         | No         |
| Steven       | Graham        | No         |
| Steven       | Pam           | Yes        |
| ...          | ...           | ...        |
| Ian          | Pippa         | Yes        |
| ...          | ...           | ...        |
| Anna         | Nikki         | Yes        |
| ...          | ...           | ...        |
| Nikki        | Anna          | yes        |

| First person        | Second person | Sister of? |
|---------------------|---------------|------------|
| Steven              | Pam           | Yes        |
| Graham              | Pam           | Yes        |
| Ian                 | Pippa         | Yes        |
| Brian               | Pippa         | Yes        |
| Anna                | Nikki         | Yes        |
| Nikki               | Anna          | Yes        |
| <i>All the rest</i> |               | No         |

*Closed-world assumption*

# A full representation in one table

| First person |        |         |         | Second person |        |         |         | Sister of? |
|--------------|--------|---------|---------|---------------|--------|---------|---------|------------|
| Name         | Gender | Parent1 | Parent2 | Name          | Gender | Parent1 | Parent2 |            |
| Steven       | Male   | Peter   | Peggy   | Pam           | Female | Peter   | Peggy   | Yes        |
| Graham       | Male   | Peter   | Peggy   | Pam           | Female | Peter   | Peggy   | Yes        |
| Ian          | Male   | Grace   | Ray     | Pippa         | Female | Grace   | Ray     | Yes        |
| Brian        | Male   | Grace   | Ray     | Pippa         | Female | Grace   | Ray     | Yes        |
| Anna         | Female | Pam     | Ian     | Nikki         | Female | Pam     | Ian     | Yes        |
| Nikki        | Female | Pam     | Ian     | Anna          | Female | Pam     | Ian     | Yes        |
| All the rest |        |         |         |               |        |         |         | No         |

**If second person's gender = female  
and first person's parent = second person's parent  
then sister-of = yes**

# Generating a flat file

- Process of flattening called “denormalization”
  - ♦ Several relations are joined together to make one
- Possible with any finite set of finite relations
- Problematic: relationships without pre-specified number of objects
  - ♦ Example: concept of *nuclear-family*
- Denormalization may produce spurious regularities that reflect structure of database
  - ♦ Example: “supplier” predicts “supplier address”

# The “ancestor-of” relation

| First person |        |        |        | Second person |        |                    |         | Ancestor of? |
|--------------|--------|--------|--------|---------------|--------|--------------------|---------|--------------|
| Name         | Gender | Parent | Parent | Name          | Gender | Parent             | Parent2 |              |
| Peter        | Male   | ?      | ?      | Steven        | Male   | Peter <sup>1</sup> | Peggy   | Yes          |
| Peter        | Male   | ?      | ?      | Pam           | Female | Peter              | Peggy   | Yes          |
| Peter        | Male   | ?      | ?      | Anna          | Female | Pam                | Ian     | Yes          |
| Peter        | Male   | ?      | ?      | Nikki         | Female | Pam                | Ian     | Yes          |
| Pam          | Female | Peter  | Peggy  | Nikki         | Female | Pam                | Ian     | Yes          |
| Grace        | Female | ?      | ?      | Ian           | Male   | Grace              | Ray     | Yes          |
| Grace        | Female | ?      | ?      | Nikki         | Female | Pam                | Ian     | Yes          |
|              |        |        |        |               |        |                    |         | Yes          |
|              |        |        |        |               |        |                    |         | No           |

*Other positive examples here*

*All the rest*

# Recursion

- Infinite relations require recursion

```
If person1 is a parent of person2  
    then person1 is an ancestor of person2
```

```
If person1 is a parent of person2  
    and person2 is an ancestor of person3  
    then person1 is an ancestor of person3
```

- Appropriate techniques are known as “inductive logic programming”
  - ♦ (e.g. Quinlan’s FOIL)
  - ♦ Problems: (a) noise and (b) computational complexity

# What's in an attribute?

- Each instance is described by a fixed predefined set of features, its “attributes”
- But: number of attributes may vary in practice
  - ♦ Possible solution: “irrelevant value” flag
- Related problem: existence of an attribute may depend of value of another one
- Possible attribute types (“levels of measurement”):
  - ♦ *Nominal, ordinal, interval and ratio*

# Nominal quantities

- Values are distinct symbols
  - ♦ Values themselves serve only as labels or names
  - ♦ *Nominal* comes from the Latin word for name
- Example: attribute “outlook” from weather data
  - ♦ Values: “sunny”, “overcast”, and “rainy”
- No relation is implied among nominal values (no ordering or distance measure)
- Only equality tests can be performed

# Ordinal quantities

- Impose order on values
- But: no distance between values defined
- Example:  
attribute “temperature” in weather data
  - ♦ Values: “hot” > “mild” > “cool”
- Note: addition and subtraction don’t make sense
- Example rule:  
temperature < hot  $\Rightarrow$  play = yes
- Distinction between nominal and ordinal not always clear (e.g. attribute “outlook”)

# Interval quantities

- Interval quantities are not only ordered but measured in fixed and equal units
- Example 1: attribute “temperature” expressed in degrees Fahrenheit
- Example 2: attribute “year”
- Difference of two values makes sense
- Sum or product doesn’t make sense
  - ♦ Zero point is not defined!

# Ratio quantities

- Ratio quantities are ones for which the measurement scheme defines a zero point
- Example: attribute “distance”
  - ♦ Distance between an object and itself is zero
- Ratio quantities are treated as real numbers
  - ♦ All mathematical operations are allowed
- But: is there an “inherently” defined zero point?
  - ♦ Answer depends on scientific knowledge (e.g. Fahrenheit knew no lower limit to temperature)

# Attribute types used in practice

- Most schemes accommodate just two levels of measurement: nominal and ordinal
- Nominal attributes are also called “categorical”, “enumerated”, or “discrete”
  - ♦ But: “enumerated” and “discrete” imply order
- Special case: dichotomy (“boolean” attribute)
- Ordinal attributes are called “numeric”, or “continuous”
  - ♦ But: “continuous” implies mathematical continuity

# Metadata

- Information about the data that encodes background knowledge
- Can be used to restrict search space
- Examples:
  - ♦ Dimensional considerations  
(i.e. expressions must be dimensionally correct)
  - ♦ Circular orderings  
(e.g. degrees in compass)
  - ♦ Partial orderings  
(e.g. generalization/specialization relations)

# Preparing the input

- Denormalization is not the only issue
- Problem: different data sources (e.g. sales department, customer billing department, ...)
  - ♦ Differences: styles of record keeping, conventions, time periods, data aggregation, primary keys, errors
  - ♦ Data must be assembled, integrated, cleaned up
  - ♦ “Data warehouse”: consistent point of access
- External data may be required (“overlay data”)
- Critical: type and level of data aggregation

# The ARFF format

```
%  
% ARFF file for weather data with some numeric features  
%  
@relation weather  
  
@attribute outlook {sunny, overcast, rainy}  
@attribute temperature numeric  
@attribute humidity numeric  
@attribute windy {true, false}  
@attribute play? {yes, no}  
  
@data  
sunny, 85, 85, false, no  
sunny, 80, 90, true, no  
overcast, 83, 86, false, yes  
...
```

# Additional attribute types

- ARFF supports *string* attributes:

```
@attribute description string
```

- ◆ Similar to nominal attributes but list of values is not pre-specified
- It also supports *date* attributes:

```
@attribute today date
```

- ◆ Uses the ISO-8601 combined date and time format *yyyy-MM-dd-THH:mm:ss*

# Sparse data

- In some applications most attribute values in a dataset are zero
  - ♦ E.g.: word counts in a text categorization problem
- ARFF supports sparse data

```
0, 26, 0, 0, 0, 0, 63, 0, 0, 0, "class A"  
0, 0, 0, 42, 0, 0, 0, 0, 0, 0, "class B"
```

```
{1 26, 6 63, 10 "class A"}  
{3 42, 10 "class B"}
```

- This also works for nominal attributes (where the first value corresponds to “zero”)

# Attribute types

- Interpretation of attribute types in ARFF depends on learning scheme
  - ♦ Numeric attributes are interpreted as
    - ordinal scales if less-than and greater-than are used
    - ratio scales if distance calculations are performed (normalization/standardization may be required)
  - ♦ Instance-based schemes define distance between nominal values (0 if values are equal, 1 otherwise)
- Integers in some given data file: nominal, ordinal, or ratio scale?

# Nominal vs. ordinal

- Attribute “age” nominal

```
If age = young and astigmatic = no  
and tear production rate = normal  
then recommendation = soft
```

```
If age = pre-presbyopic and astigmatic = no  
and tear production rate = normal  
then recommendation = soft
```

- Attribute “age” ordinal  
(e.g. “young” < “pre-presbyopic” < “presbyopic”)

```
If age ≤ pre-presbyopic and astigmatic = no  
and tear production rate = normal  
then recommendation = soft
```

# Missing values

- Frequently indicated by out-of-range entries
  - ♦ Types: unknown, unrecorded, irrelevant
  - ♦ Reasons:
    - malfunctioning equipment
    - changes in experimental design
    - collation of different datasets
    - measurement not possible
- Missing value may have significance in itself (e.g. missing test in a medical examination)
  - ♦ Most schemes assume that is not the case:  
“missing” may need to be coded as additional value

# Inaccurate values

- Reason: data has not been collected for mining it
- Result: errors and omissions that don't affect original purpose of data (e.g. age of customer)
- Typographical errors in nominal attributes  $\Rightarrow$  values need to be checked for consistency
- Typographical and measurement errors in numeric attributes  $\Rightarrow$  outliers need to be identified
- Errors may be deliberate (e.g. wrong zip codes)
- Other problems: duplicates, stale data

# Getting to know the data

- Simple visualization tools are very useful
  - ♦ Nominal attributes: histograms (Distribution consistent with background knowledge?)
  - ♦ Numeric attributes: graphs (Any obvious outliers?)
- 2-D and 3-D plots show dependencies
- Need to consult domain experts
- Too much data to inspect? Take a sample!
