ABSTRACT

SweetDeal is a rule-based approach to representation of business contracts that enables software agents to create, evaluate, negotiate, and execute contracts with substantial automation and modularity. It builds upon the situated courteous logic programs knowledge representation in RuleML, the emerging standard for Semantic Web XML rules. Here, we newly extend the SweetDeal approach by also incorporating process knowledge descriptions whose ontologies are represented in DAML+OIL (emerging standard for Semantic Web ontologies) thereby enabling more complex contracts with behavioral provisions, especially for handling exception conditions (e.g., late delivery or non-payment) that might arise during the execution of the contract. This provides a foundation for representing and automating deals about services – in particular, about Web Services, so as to help search, select, and compose them. Our system is also the first to combine emerging Semantic Web standards for knowledge representation of rules (RuleML) with ontologies (DAML+OIL) for a practical e-business application domain, and further to do so with process knowledge. This also newly fleshes out the evolving concept of *Semantic Web Services*. A prototype (soon public) is running.

Categories and Subject Descriptors

I.2.4 [Knowledge Representation Formalisms and Methods]: Representation languages, Representations (procedural and rule-based); **H.4.m [Information Systems Applications]:** Miscellaneous.

General Terms

Design, Theory, Languages, Management, Standardization, Economics, Human Factors, Algorithms, Documentation.

Keywords

Electronic contracts, electronic commerce, XML, Semantic Web, Web Services, Semantic Web Services, knowledge representation,

intelligent software agents, rules, logic programs, ontologies, business process automation, process descriptions, process knowledge, RDF, Description Logic, DAML+OIL, OWL, knowledge-based, declarative.

1. INTRODUCTION

A key challenge in e-commerce is to specify the terms of the deal between buyers and sellers, e.g., pricing and description of goods/services. In previous work [1] [2], we have developed an approach that automates (parts or all of) such business contracts by representing and communicating them as modular sets of declarative logic-program rules. This approach enables software agents to create, evaluate, negotiate, and execute contracts with substantial automation and modularity. It enables a high degree of reuse of the contract description for multiple purposes in the overall process of contracting: discovery, negotiation, evaluation, execution, and monitoring. That approach, now called SweetDeal, builds upon our situated courteous logic programs (SCLP) knowledge representation in RuleML [3], the emerging standard for Semantic Web XML rules that we (first author) co-lead. SweetDeal also builds upon our SweetRules prototype system for rules inferencing and inter-operability in SCLP RuleML [4].¹

In this paper, we newly extend the SweetDeal approach by also incorporating process knowledge descriptions whose ontologies are represented in DAML+OIL [5]. OWL [30], the emerging Semantic Web standard for ontologies from the World Wide Web Consortium (W3C), is based very closely on DAML+OIL; their fundamental knowledge representation is Description Logic (DL), an expressive fragment of first-order logic, and both encode this syntactically in Resource Description Framework (RDF) [33]. RDF is a somewhat cleaner, simpler, and more expressive language for labeled directed graphs than basic XML, and is itself in turn easily encoded in XML. We chose DAML+OIL because it was more stable during the period we performed this work; indeed, when we began this work, OWL did not yet exist.

Our extension of the SweetDeal approach to incorporate such process descriptions enables more complex contracts with behavioral provisions, especially for handling exception conditions that

¹ SweetDeal is fairly unique in its approach and capabilities; for related work on it, see [1] [2].

might arise during the execution of the contract. For example, a contract can first identify possible exceptions like late delivery or non-payment. Next, it can specify handlers to find or fix these exceptions, such as contingency payments, escrow services, prerequisite-violation detectors, and notifications. Our rule-based representation enables software agents in an electronic marketplace to create, evaluate, negotiate, and execute such complex contracts with substantial automation, and to reuse the same (declarative) knowledge for multiple purposes. In particular, our approach provides a foundation for representing and automating *deals about services* – including about electronic services, e.g., Web Services – so as to help search, select, and compose them. It thereby points the way to how and why to combine Semantic Web techniques [6] with Web Services techniques [7] to create *Semantic Web Services* [29], a topic which the DAML-Services effort [8] and the Web Service Modelling Framework (WSMF) effort [28] have also been addressing (although not yet much in terms of describing contractual deal aspects).

Our SweetDeal system is also the first to combine emerging Semantic Web standards for knowledge representation of rules (RuleML) with ontologies (DAML+OIL) knowledge for a practical e-business application domain, and further to do so with process knowledge. The process knowledge ontology (e.g., about exceptions and handlers) is drawn from the MIT Process Handbook [9], a previously-existing repository unique in its large content and frequent use by industry business process designers. This is the first time that the MIT Process Handbook has been automated using XML or powerful logical knowledge representation.

This paper is drawn from a larger effort on SweetDeal whose most recent portion (second author's masters thesis) defined and implemented a software *market agent* that creates contract proposals in a semi-automated manner (i.e., in support of a human user) by combining reusable modular contract provisions, called *contract fragments*, from a queryable *contract repository* with process knowledge from a queryable *process repository*. This addresses the negotiation process in an overall interaction architecture for an agent marketplace with such rule-based contracts. A prototype of the SweetDeal system is running. We intend to make the prototype publicly available in the near future.

2. SWEETRULES, RULEML, SWEETDEAL: MORE BACKGROUND

SweetDeal is part of our larger effort SWEET, acronym for “Semantic Web Enabling Technology”, and is prototyped on top of SweetRules. Our earlier SweetRules prototype was the first to implement SCLP RuleML inferencing and also was the first to implement translation of (SCLP) RuleML to and from multiple heterogeneous rule systems. SweetRules enables bi-directional translation from SCLP RuleML to: XSB, a Prolog rule system [10]; Smodels, a forward logic-program rule engine [11]; the IBM CommonRules rule engine, a forward SCLP system [12]; and Common Logic (formerly known as Knowledge Interchange Format (KIF)), an emerging ISO industry standard for knowledge interchange in classical logic [13].² The latest component of SweetRules is SweetJess [14] which aims to enable bi-directional translation to Jess, a popular open-source forward production-rule

system in Java [15]. The SweetJess prototype is publicly available free for Web download.

The SCLP case of RuleML is expressively powerful. The courteous extension of logic programs enables prioritized conflict handling and thereby facilitates modularity in specification, modification, merging, and updating. The situated extension of logic programs enables procedural attachments for “sensing” (testing rule antecedents) and “effecting” (performing actions triggered by conclusions). Merging and modification is important specifically for automated (“agent”) contracts, because contracts are often assembled from reusable provisions, from multiple organizational sources, and then tweaked. Updating is important because a contract is often treated as a template to be filled in. For example, before an on-line auction is held a contract template is provided for the good/service being auctioned. Then when the auction closes, the template is filled in with the winning price and the winner's name, address, and payment method. Indeed, in [2] we show how to use SCLP to represent contracts in this dynamically updated manner, for a real auction server – U. Michigan's AuctionBot – and the semi-realistic domain of a Trading Agent Competition about travel packages. More generally, the design of SCLP as a knowledge representation (KR) grew out of a detailed requirements analysis [1] for rules in automated contracts and business policies. The RuleML standards effort is being pursued in informal cooperation with: (1) the W3C's Semantic Web Activity, which has now included rules in its charter along with ontologies; (2) the DARPA Agent Markup Language Program (DAML) [16]; (3) the Joint US/EU ad hoc Agent Markup Language Committee [31] which designed DAML+OIL; and (4) the Oasis e-business standards body [32].

3. OVERVIEW OF THE REST OF THE PAPER

In section 4, we review the MIT Process Handbook (PH) [9] [17], and Klein *et al*'s extension of it to treat exception conditions in contracts [18]. In section 5, we newly show how to represent the Process Handbook's process ontology (including about exceptions) in DAML+OIL, giving some examples. In section 6, we describe our development of an additional ontology specifically about contracts, again giving examples in DAML+OIL. This contract ontology extends and complements the PH process ontology. In section 7, we newly give an approach to using DAML+OIL ontology as the predicates etc. of RuleML rules. In section 8, we newly show how to use the DAML+OIL process ontology, including about contracts and exceptions, as the predicates etc. of RuleML rules, where a ruleset represents part or all of a (draft or final) contract with exceptions and exception handlers. We illustrate by giving a long-ish example of such a contract ruleset whose rule-based contingency provisions include detecting and penalizing late delivery exceptions, thus providing means to deter or adjudicate a late delivery. In section 9, we give conclusions. In section 10, we discuss directions for future work. \

4. MIT PROCESS HANDBOOK (PH)

In this section, we review the MIT Process Handbook (PH) [9] [17], and Klein *et al*'s extension of it to treat exception conditions in contracts [18].

The MIT Process Handbook (PH) is a previously-existing knowledge repository of business process knowledge. It is primarily textual and oriented to human-readability although with some useful automation for knowledge management using taxonomic structure. Among automated repositories of business process knowledge, it is unique (to our knowledge) in having a large

² SweetRules is built in Java. It uses XSLT [22] and components of the IBM CommonRules library.

amount of content and having been frequently used practically by industry business process designers from many different companies. Previous to our work in SweetDeal, however, its content had never been automated in XML, nor had that content ever been represented in any kind of powerful logical knowledge representation – the closest was its use of a fairly conventional Object-Oriented (OO) style of taxonomic hierarchy, as a tool to organize its content for retrieval and browsing.

The Handbook describes and classifies major business processes using the organizational concepts of *decomposition*, *dependencies*, and *specialization*. The Handbook models each process as a collection of activities that can be decomposed into sub-activities, which may themselves be processes. In turn, coordination is modeled as the management of dependencies that represent flows of control, data, or material between activities. Each dependency is managed by a coordination mechanism, which is the process that controls its resource flow.

Finally, processes are arranged into a generalization-specialization taxonomy, with generic processes at the top and increasingly specialized processes underneath. Each specialization automatically inherits the properties of its parents, except where it explicitly adds or changes a property. This is similar to taxonomic class hierarchies having default inheritance³, such as in many Object-Oriented (OO) programming languages, knowledge representations (KR's) and information modeling systems. Note that the taxonomy is not a tree, as an entity may have multiple parents. In general, there thus is multiple inheritance. For example, BuyAsALargeBusiness is a subclass of both Buy and ManageEntity. The figure below shows a part of the taxonomy with some of the specializations for the “Sell” process. Note the first generation of children of “Sell” are questions; these are classes used as intermediate categories, analogous to virtual classes (or pure interfaces) in OO programming languages. Since there is multiple inheritance, it is easy to provide several such “cross-cutting” dimensions of categories along which to organize the hierarchy.

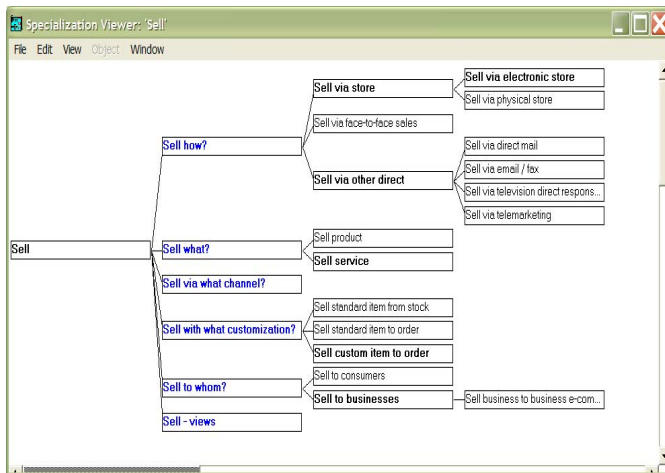

Figure 1: Some specializations of “Sell” in the MIT Process Handbook.

Exception Conditions

The terms of any contract establish a set of commitments between the parties involved for the execution of that contract. When a contract is executed, these commitments are sometimes violated.

³ a.k.a. “inheritance with exceptions”, a.k.a. “non-monotonic inheritance”

Often contracts, or the laws or automation upon which they rely, specify how such violation situations should be handled.

Building upon the Process Handbook, Klein *et al* [18] consider these violations to be coordination failures – called “exceptions” – and introduces the concept of exception handlers, which are processes that manage particular exceptions. We in turn build upon Klein *et al*’s approach. When an exception occurs during contract execution, an exception handler associated with that exception may be invoked.

For example, in a given contract (agreement), company A agrees to pay \$50 per unit for 100 units of company B’s product, and B agrees to deliver within 15 days (commitments). However, due to unforeseen circumstances, when the contract is actually performed, B only manages to deliver in 20 days (exception). As a result, B pays \$1000 to A as compensation for the delay (exception handler).

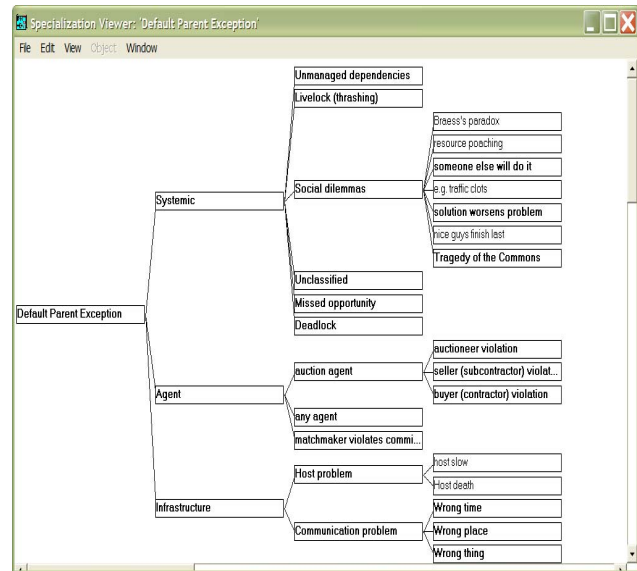

Figure 2: Some exceptions in the MIT Process Handbook.

There are four classes of exception handlers in [18]. For an exception that has not occurred yet, one can use:

- Exception anticipation processes, which identify situations where the exception is likely to occur.
- Exception avoidance processes, which decrease or eliminate the likelihood of the exception.

For an exception that has already occurred, one can use:

- Exception detection processes, which detect when the exception has actually occurred.
- Exception resolution processes, which resolve the exception once it has occurred.

[18] extends the MIT Process Handbook with an exception taxonomy. Every process may be associated via *hasException* links to its potential exceptions (zero or more), which are the characteristic ways in which its commitments may be violated. *hasException* should be understood as “has potential exception”. Similar to the process taxonomy, exceptions are arranged in a specialization hierarchy, with generic exceptions on top and more specialized exceptions underneath. In turn, each exception is associated (via an *isHandledBy* link) to the processes (*exception handlers*) that can be used to deal with that exception. Since handlers are processes, they may have their own characteristic exceptions.

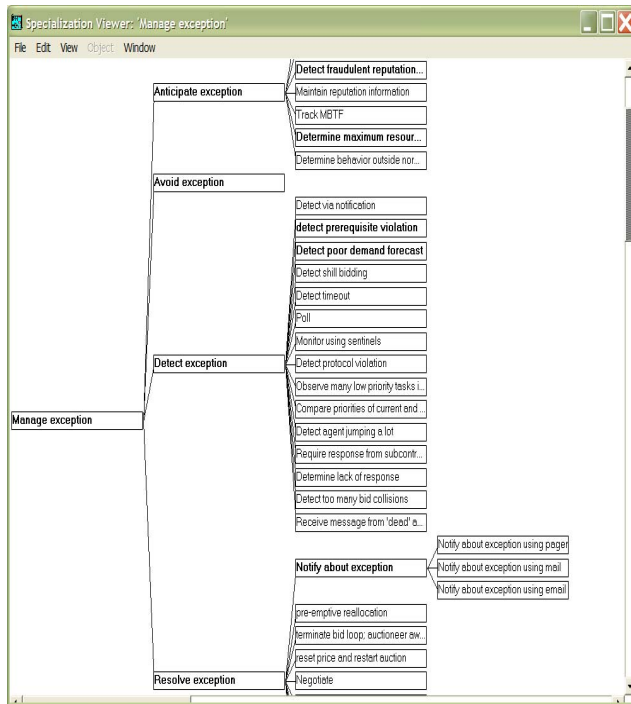

Figure 3: Some exception handlers in the MIT Process Handbook.⁴

Following the general style of (multiple) inheritance in the MIT Process Handbook, the exceptions associated with a process are inherited by the specializations of that process. Similarly, the handlers for an exception are inherited by the specializations of that exception.

5. REPRESENTING THE PH PROCESS ONTOLOGY IN DAML+OIL

In this section, we newly show how to represent the Process Handbook's process ontology (including about exceptions) in DAML+OIL, giving some examples. This ontology is given a URI of <http://xmlcontracting.org/pr.daml>, where "pr" stands for "process". We have registered the xmlcontracting.org domain name and are in the process of setting up the web site. For the current full version of this ontology, and pointer to the xmlcontracting.org site when it is indeed up, please see the first author's website.

We begin with some DAML+OIL headers:

```
<?xml version="1.0" ?>
<rdf:RDF
  xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"
  xmlns:rdfs="http://www.w3.org/2000/01/rdf-schema#"
  xmlns:daml="http://www.daml.org/2001/03/daml+oil#"
  xmlns="http://xmlcontracting.org/pr.daml#" >
  <daml:Ontology rdf:about="" >
```

```
<daml:imports
  rdf:resource="http://www.daml.org/2001/03/daml+oil" />
</daml:Ontology>
```

Next we define some main concepts in the MIT Process Handbook as top-level classes:

```
<daml:Class rdf:ID="Process">
  <rdfs:comment>A process</rdfs:comment>
</daml:Class>

<daml:Class rdf:ID="CoordinationMechanism">
  <rdfs:comment>A process that manages activities
  between multiple agents</rdfs:comment>
</daml:Class>

<daml:Class rdf:ID="Exception">
  <rdfs:comment>A violation of an inter-agent
  commitment</rdfs:comment>
</daml:Class>

<daml:Class rdf:ID="ExceptionHandler">
  <rdfs:subClassOf rdf:resource="#Process"/>
  <rdfs:comment>A process that helps to manage a
  particular exception</rdfs:comment>
</daml:Class>
```

Then we define the relations between concepts as object properties:

```
<daml:ObjectProperty rdf:ID="hasException">
  <rdfs:comment>Has a potential
  exception</rdfs:comment>
  <rdfs:domain rdf:resource="#Process" />
  <rdfs:range rdf:resource="#Exception" />
</daml:ObjectProperty>

<daml:ObjectProperty rdf:ID="isHandledBy">
  <rdfs:comment>Can potentially be handled, in
  some way or aspect, by</rdfs:comment>
  <rdfs:domain rdf:resource="#Exception" />
  <rdfs:range rdf:resource="#ExceptionHandler" />
</daml:ObjectProperty>
```

Specializations are expressed as subclasses⁶:

```
<daml:Class rdf:ID="SystemCommitmentViolation">
  <rdfs:subClassOf rdf:resource="#Exception"/>
  <rdfs:comment> Violation of a commitment made by
  the system operator to create an environment well-
  suited to the task at hand. </rdfs:comment>
</daml:Class>

<daml:Class rdf:ID="AgentCommitmentViolation">
  <rdfs:subClassOf rdf:resource="#Exception"/>
  <rdfs:comment> Violation of a commitment that an
  agents makes to other agents.
  </rdfs:comment>
</daml:Class>
```

⁴ *Track MBTF* is a typo in the MIT Process Handbook. It should be *Track MTBF* (mean time between failures) instead.

⁶ In Figure 2 (in Section 3), *SystemCommitmentViolation* and *AgentCommitmentViolation* are shown as "Systemic" and "Agent", respectively.

The Process Handbook expects each specialization to inherit the properties of its parent. The DAML+OIL semantics provide this automatically since it entails monotonic (strict) inheritance of such properties.

The Process Handbook is quite large (order of magnitude 10,000 classes). We have (so far) represented in DAML+OIL a relevant fragment amounting to a small percentage of its content. Only some of that fragment is shown in this paper, however. For the full details, see the first author's website.

6. CONTRACT ONTOLOGY

In this section, we describe our development of an additional process ontology specifically about contracting concepts and relations, again giving examples in DAML+OIL. This *contract ontology* extends and complements the PH process ontology. We give it the URI <http://xmlcontracting.org/sd.daml>, where “sd” stands for “SweetDeal”. For the current file version of this ontology, and pointer to the xmlcontracting.org site when it is indeed up, please see the first author's website.

Again we begin with some DAML+OIL header statements. Notice that we import the PH process ontology:

```
<?xml version='1.0' encoding='ISO-8859-1'?>
<rdf:RDF
  xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"
  xmlns:rdfs="http://www.w3.org/2000/01/rdf-schema#"
  xmlns:daml="http://www.daml.org/2001/03/daml+oil#"
  xmlns="http://xmlcontracting.org/sd.daml#"
  ><daml:Ontology rdf:about="">
  <daml:imports
    rdf:resource="http://www.daml.org/2001/03/daml+oil" />
  <daml:imports
    rdf:resource="http://xmlcontracting.org/pr.daml" />
</daml:Ontology>
```

We view a contract as a specification for one or more processes. Accordingly, we define the *Contract* class and a *specFor* relation that links a contract to its process(es):

```
<daml:Class rdf:ID="Contract">
  <rdfs:subClassOf>
    <daml:Restriction daml:minCardinality="1">
      <daml:onProperty rdf:resource="#specFor" />
    </daml:Restriction>
  </rdfs:subClassOf>
</daml:Class>
<daml:ObjectProperty rdf:ID="specFor">
  <rdfs:domain rdf:resource="#Contract" />
  <rdfs:range
    rdf:resource="http://xmlcontracting.org/pr.daml#Process" />
</daml:ObjectProperty>
```

To represent the common special case of contracts that specify only one process, we define *ContractForOneProcess*, using a `daml:cardinality` restriction to limit the *specFor* relation to exactly one process:

```
<daml:Class rdf:ID="ContractForOneProcess">
  <rdfs:subClassOf rdf:resource="#Contract" />
  <rdfs:subClassOf>
```

```
<daml:Restriction daml:cardinality="1">
  <daml:onProperty rdf:resource="#specFor" />
</daml:Restriction>
</rdfs:subClassOf>
</daml:Class>
```

A contract represents the “terms and conditions” that the parties have agreed upon (typically) *before* performing the contract. E.g., they have come to agreement during a negotiation before their contract commitments actually come due. We define a separate concept, *ContractResult*, to represent the state of how the contract was actually carried out. For example, *ContractResult* could describe the actual shipping date, the quality of the received goods, the amount of payment received, etc.

```
<daml:Class rdf:ID="ContractResult" />
<daml:ObjectProperty rdf:ID="result">
  <rdfs:domain rdf:resource="#Contract" />
  <rdfs:range rdf:resource="#ContractResult" />
</daml:ObjectProperty>
```

The process ontology provides the *hasException* relation to indicate that a process *could* have a particular exception. How do we indicate that an exception has occurred during contract execution? We define the *exceptionOccurred* relation on *ContractResult* to denote that the exception happened as the contract was being carried out:

```
<daml:ObjectProperty rdf:ID="exceptionOccurred">
  <daml:domain
    rdf:resource="http://xmlcontracting.org/pr.daml#ContractResult" />
  <daml:range
    rdf:resource="http://xmlcontracting.org/pr.daml#Exception" />
</daml:ObjectProperty>
```

Finally, we introduce some relations to specify the purpose that an exception handler fulfills. A *DetectException* handler is intended to detect certain exception classes, an *AnticipateException* handler is intended to anticipate certain exception classes, etc. We want to identify exception classes, not exception instances. We thus make the range be the class *Class*.⁷

```
<daml:ObjectProperty rdf:ID="detectsException">
  <daml:domain
    rdf:resource="http://xmlcontracting.org/pr.daml#DetectException" />
  <daml:range
    rdf:resource="http://www.daml.org/2001/03/daml+oil#Class" />
</daml:ObjectProperty>
<daml:ObjectProperty
  rdf:ID="anticipatesException">
  <daml:domain
    rdf:resource="http://xmlcontracting.org/pr.daml#AnticipateException" />
```

⁷ This is based on the interpretation that an instance of class *Class* is a class, something which we could not find explicitly addressed in the DAML+OIL reference manual. Also, ideally, we would restrict the range to subclasses of *Exception*, but we did not see a straightforward way to do this in the current version of DAML+OIL.

```

    <daml:range
rdf:resource="http://www.daml.org/2001/03/daml+oil
#Class"/>
</daml:ObjectProperty>
<daml:ObjectProperty rdf:ID="avoidsException">
    <daml:domain
rdf:resource="http://xmlcontracting.org/pr.daml#Avo
idException"/>
    <daml:range
rdf:resource="http://www.daml.org/2001/03/daml+oil
#Class"/>
</daml:ObjectProperty>
    <daml:ObjectProperty rdf:ID="resolvesException">
    <daml:domain
rdf:resource="http://xmlcontracting.org/pr.daml#Re
solveException"/>
    <daml:range
rdf:resource="http://www.daml.org/2001/03/daml+oil
#Class"/>
</daml:ObjectProperty>

```

There are a number of other interesting concepts and ontological statements about contracts that we have developed in our Sweet-Deal Contract Ontology, but space prevents us from detailing them further here.

7. INTEGRATING DAML+OIL ONTOLOGIES INTO RULEML RULES

In this section, we briefly describe the technical representational approach for the integration of the DAML+OIL ontologies into the RuleML rules, in which the RuleML rules are specified “on top of” the DAML+OIL ontology. In the next section, we give examples of RuleML contract rules that make use of DAML+OIL process ontologies.

A DAML+OIL class is treated as a unary predicate. A DAML+OIL property is treated as a binary predicate. Assertions about instances in a class are treated as rule atoms (e.g., facts) in which the class predicate appears. Assertions about property links between class instances are treated as rule atoms in which the property predicate appears. RuleML permits a predicate symbol (or a logical function symbol) to be a URI; we make heavy use of this capability since the names of DAML+OIL classes are URI’s. To our knowledge, ours is the first published description and example of such integration of DAML+OIL into RuleML, and one of the first two published descriptions and examples of combination of DAML+OIL with a non-monotonic rule KR -- the other being [19] which was done independently.⁸

A natural question arises: how to define formally the semantics of such integration, i.e., of the *hybrid* KR formed by combining LP rules on top of DL ontologies (or, similarly, by combining Horn FOL rules on top of DL ontologies). One might view this through the lens of the rule KR’s semantics and/or through the lens of the ontology KR’s semantics. Knowledge specified in a set of premise rules *R1* together with a set of premise DL axioms *O1* may entail knowledge *O2* expressible in DL that goes beyond what was entailed by *O1* alone, and likewise may entail knowl-

edge *R2* expressible in LP that goes beyond what was entailed by *R1* alone. It is also possible, in general, for inconsistency to arise from the combination of *R1* with *O1*, even though each is consistent in itself. Such *O2*, *R2*, and potential inconsistency can all be avoided by suitably expressively restricting the ontologies (or the rules) -- to be *Description Logic Programs (DLP)*. Elsewhere [27] we give details about DLP. A somewhat similar hybrid KR is addressed in [19].

8. RULEML CONTRACTS WITH EXCEPTIONS USING THE PROCESS AND CONTRACT ONTOLOGIES

In this section, we newly show how to use the DAML+OIL process ontology, including about contracts and exceptions, as the predicates etc. of RuleML rules, where a ruleset represents part or all of a (draft or final) contract that has exceptions and exception handlers.

We illustrate by giving a long-ish example of such a contract rule-set whose rule-based contingency provisions include detecting and penalizing late delivery exceptions, thus providing means to deter or adjudicate a late delivery.

RuleML, like most XML, is fairly verbose. For ease of human-readability, as well as to save paper space, we give our RuleML examples in a Prolog-like syntax that maps straightforwardly to RuleML. More precisely, this syntax is IBM CommonRules V3.0 “SCLPfile” format, extended to support URI’s as logical predicate (and function) symbols and to support names for rule subsets (i.e., “modules”). “<-“ stands for implication, i.e., “if”. “;” ends a rule statement. The prefix “?” indicates a logical variable. “/*...*/” encloses a comment line. “<...>” encloses a rule label (name) or rule module label. “{...}” encloses a rules module. Rule labels identify rules for editing and prioritized conflict handling, for example to facilitate the modular modification of contract provisions. Module labels are used to manage the merging of multiple rule modules to form a contract.

In the examples below, DAML+OIL classes and properties, taken from the PH process ontology and contract (process) ontology, are used as predicate symbols.

Let’s begin with an example draft contract `co123` where Acme is purchasing 100 units of plastic product #425 from Plastics Etc. at \$50 per unit. Acme requires Plastics Etc. to ship the product no later than three days after the order is placed⁹. We specify this draft contract as the following rulebase (i.e., set of rules):

```

http://xmlcontracting.org/sd.daml#Contract(co123);
http://xmlcontracting.org/sd.daml#specFor(co123,co
123_process);
http://xmlcontracting.org/sd.daml#BuyWithBilateral
Negotiation(co123_process);
http://xmlcontracting.org/sd.daml#result(co123,col
23_res);
buyer(co123,acme);
seller(co123,plastics_etc);
product(co123,plastic425);

```

⁸ We (first author) gave oral presentations of this approach in communal design discussions about DAML and about RuleML since when those discussions began in summer 2000. The overall goal of rules on top of ontologies has, indeed, been a communal goal in those discussions since then.

⁹ Here we use a relative date (e.g. 3) rather than an absolute date (e.g. 2002-04-02), for sake of simplicity and because the rule engine that we are using in our prototype (IBM CommonRules) does not (yet) provide convenient date arithmetic functions.

```

shippingDate(col23,3); /* i.e. 3 days after the
order is placed */
price(col23,50);
quantity(col23,100);
/* base payment = price * quantity */
payment(?R,base,?Payment) <-

```

```

http://xmlcontracting.org/sd.daml#result(col23,?R)
AND
    price(col23,?P) AND quantity(col23,?Q) AND
    Multiply(?P,?Q,?Payment) ;

```

Continuing our example, suppose the seller wants to include a contract provision to penalize late delivery – so as to reassure the buyer. First we add some rules to declare that this contract has an exception instance *e1* that is an instance of the *LateDelivery* class from the process ontology:

```

http://xmlcontracting.org/pr.daml#hasException(col
23_process,e1);
http://xmlcontracting.org/pr.daml#LateDelivery(e1)
;

```

Note that the actual occurrence of an exception is associated with a contract result, as opposed to its potential occurrence which is associated with the contract (agreement)’s process. *hasException* specifies the potential occurrence. We will see below more about the actual occurrence.

Next, we give a rules module (i.e., a set of additional rules to include in the overall draft contract ruleset) that specifies a basic kind of exception handler process – to detect the late delivery.

In our approach, exception handler processes themselves may be rule-based (in part or totally), although in general they need not be rule-based at all. The exception handler *detectLateDelivery* is rule-based in this example. Below, the variable *?CO* stands for a contract, *?R* for a contract result, *?EI* for an exception instance, *?PI* for a process instance, *?COD* for a promised contract shipping date, and *?RD* for a contract result’s actual shipping date.

```

<detectLateDelivery_module> {

/* detectLateDelivery is an instance of
DetectPrerequisiteViolation (and thus of
DetectException, ExceptionHandler, and Process) */
http://xmlcontracting.org/pr.daml#DetectPrerequisiteViolation(
    detectLateDelivery) ;
/* detectLateDelivery is intended to detect
exceptions of class LateDelivery */
http://xmlcontracting.org/sd.daml#detectsException(
detectLateDelivery,
    http://xmlcontracting.org/pr.daml#LateDelivery);
/* a rule defines the actual occurrence of a late
delivery in a contract result */
<detectLateDelivery_def>
http://xmlcontracting.org/sd.daml#exceptionOccurre
d(?R, ?EI) <-

http://xmlcontracting.org/sd.daml#specFor(?CO,?PI)
AND

```

```

http://xmlcontracting.org/pr.daml#hasException(?PI
,?EI) AND

```

```

http://xmlcontracting.org/pr.daml#LateDelivery(?EI
) AND

```

```

http://xmlcontracting.org/pr.daml#isHandledBy(?EI,
detectLateDelivery) AND
    http://xmlcontracting.org/sd.daml#result(?CO,?R)
AND
    shippingDate(?CO,?COD) AND shippingDate(?R,?RD)
AND
    greaterThan(?RD,?COD) ;
}

```

Then we add the following rule to the contract to specify *detectLateDelivery* as a handler for *e1*:

```

<detectLateDeliveryHandlesIt(e1)>

```

```

http://xmlcontracting.org/pr.daml#isHandledBy(e1,detectLateDel
ivery);

```

Merely detecting late delivery is not enough; the buyer also wants to get a penalty (partial refund) if late delivery occurs. Continuing our example, we next give a rules module to specify a penalty of \$200 per day late, via an exception handler process *lateDeliveryPenalty*. Again, this handler is itself rule-based.

```

lateDeliveryPenalty_module {

// lateDeliveryPenalty is an instance of
PenalizeForContingency (and thus of
AvoidException, ExceptionHandler, and Process)
http://xmlcontracting.org/pr.daml#PenalizeForConti
gency(
    lateDeliveryPenalty) ;
// lateDeliveryPenalty is intended to avoid
exceptions of class LateDelivery.
http://xmlcontracting.org/sd.daml#avoidsException(
lateDeliveryPenalty,
    http://xmlcontracting.org/pr.daml#LateDelivery);
// penalty = - overdueDays * 200 ; (negative
payment by buyer)
<lateDeliveryPenalty_def> payment(?R,
contingentPenalty, ?Penalty) <-

http://xmlcontracting.org/sd.daml#specFor(?CO,?PI)
AND

http://xmlcontracting.org/pr.daml#hasException(?PI
,?EI) AND

http://xmlcontracting.org/pr.daml#isHandledBy(?EI,
lateDeliveryPenalty) AND
    http://xmlcontracting.org/sd.daml#result(?CO,?R)
AND

```

```

http://xmlcontracting.org/sd.daml#exceptionOccurre
d(?R,?EI) AND
    shippingDate(?CO,?CDate) AND
shippingDate(?R,?RDate) AND
    subtract(?RDate,?CDate,?OverdueDays) AND
    multiply(?OverdueDays, 200, ?Res1) AND
multiply(?Res1, -1, ?Penalty) ;
}

```

We add a rule to specify lateDeliveryPenalty as a handler for e1:

```

<lateDeliveryPenaltyHandlesIt(e1)>
http://xmlcontracting.org/pr.daml#isHandledBy(e1,lateDeliveryPenalty);

```

During contract execution, if Plastics Etc. ships its product 8 days after the order is placed (i.e. 5 days later than the agreed-upon date), then the rules detectLateDelivery will declare that late delivery exception has occurred, which will trigger lateDeliveryPenalty to impose a penalty of \$200 per day late, totaling \$1000.

More precisely, suppose we represent the contract result as the ruleset formed by adding (to the above contract) the following “result” fact:

```
shippingdate(col23_res, 8) ;
```

Then the contract result ruleset entails various conclusions, in particular

```

http://xmlcontracting.org/sd.daml#exceptionOccurre
d(col23_res,e1) ;
payment(col23_res, contingentPenalty, -1000) ;

```

Our SweetRules prototype system, which implements SCLP RuleML inferencing, can generate these conclusions automatically.

Next, we (relatively briefly, due to space constraints) illustrate how to use prioritized conflict handling, enabled by the courteous feature of SCLP RuleML, to modularly modify the contract provisions, e.g., during bilateral negotiation. The seller might like to specify that the late delivery exception should be handled by the handler lateDeliveryRiskPayment, which imposes an up-front insurance-like discount to compensate for the risk of late delivery, basing risk upon a historical average probability distribution (defined separately) of delivery lateness. First, we define a rules module for the risk payment handler:

```

lateDeliveryRiskPayment_module {
/* lateDeliveryRiskPayment is an instance of
AvoidException (and thus of ExceptionHandler, and
Process) */
http://xmlcontracting.org/pr.daml#AvoidException(
    lateDeliveryRiskPayment) ;
/* lateDeliveryRiskPayment is intended to avoid
exceptions of class LateDelivery. */
http://xmlcontracting.org/sd.daml#avoidsException(
    lateDeliveryRiskPayment,
    http://xmlcontracting.org/sd.daml#LateDelivery) ;
/* penalty = - expected_lateness * 200 (negative
payment by buyer) */
<lateDeliveryRiskPayment_def>
payment(?R, contingentRiskPayment, ?Penalty) <-

```

```

http://xmlcontracting.org/sd.daml#specFor(?CO,?PI)
AND

```

```

http://xmlcontracting.org/sd.daml#hasException(?PI,
?EI) AND

```

```

http://xmlcontracting.org/pr.daml#isHandledBy(?EI,
lateDeliveryRiskPayment) AND

```

```

    http://xmlcontracting.org/sd.daml#result(?CO,?R)
AND

```

```

historical_probabilistically_expected_lateness(?CO,
?EOverdueDays) AND

```

```

    Multiply(?EOverdueDays, 200, ?Res1) AND
Multiply(?Res1, -1, ?Penalty);
}

```

Then we add a rule to specify lateDeliveryRiskPayment as a handler for e1:

```

<lateDeliveryRiskPaymentHandlesIt(e1)>
http://xmlcontracting.org/pr.daml#isHandledBy(e1,
lateDeliveryRiskPayment);

```

Next, we give some rules that use prioritized conflict handling to specify that late deliveries should be avoided by lateDeliveryRiskPayment rather than any other candidate avoid-type exception handlers for the late delivery exception (here, simply, lateDeliveryPenalty). We specify this using a combination of a MUTEX statement and an overrides statement that gives the lateDeliveryRiskPaymentHandlesIt(e1) rule higher priority than the lateDeliveryPenaltyHandlesIt(e1) rule.

```

/* There is at most one avoid handler for a given
exception instance. */

```

```

/* This is expressed as a MUTual EXclusion between
two potential conclusions, given certain other
preconditions. */

```

```

/* The mutex is a consistency-type integrity
constraint, which is enforced by the courteous
aspect of the semantics of the rule KR. */

```

```
MUTEX
```

```

http://xmlcontracting.org/pr.daml#isHandledBy(?EI,
?EHandler1) AND

```

```

http://xmlcontracting.org/pr.daml#isHandledBy(?EI,
?Ehandler2)

```

```
GIVEN
```

```

http://xmlcontracting.org/sd.daml#AvoidException(?
Ehandler1) AND

```

```

http://xmlcontracting.org/sd.daml#AvoidException(?
Ehandler2) ;

```

```

/* The rule lateDeliveryRiskPaymentHandlesIt(e1)
has higher priority than the rule
lateDeliveryPenaltyHandlesIt(e1). */

```

```

overrides(lateDeliveryRiskPaymentHandlesIt(e1),
lateDeliveryPenaltyHandlesIt(e1) ) ;

```

Now suppose the probabilistically expected lateness of the delivery (before actual contract execution) is 3 days. I.e., suppose the contract also includes the following fact.

```
historical_probabilistically_expected_lateness(col
23, 3) ;
```

If upon execution the modified-contract's result facts are as before – i.e., delivery is 5 days late – then the modified-contract's result entails as conclusions that the late delivery will be handled by the up-front risk payment of \$600 = (3 days * \$200).

```
payment(col23_res, contingentRiskPayment, -600) ;
```

The modified-contract's result does *not* entail that late delivery is handled by the penalty of \$1000 – as it should not. The courteous aspect of the rules knowledge representation has properly taken care of the prioritized conflict handling to enforce that the new higher-priority contract provision about risk payment dominates the provision about penalty.

9. CONCLUSIONS

To recap, this work makes novel contributions in several areas:

- Represents process knowledge from the MIT Process Handbook (PH) using an emerging Semantic Web ontology KR (DAML+OIL). This is the first time PH process knowledge has been represented using XML or powerful KR.
- Extends our previously existing SweetDeal approach to rule-based representation of contracts in SCLP/RuleML with the ability to reference such process knowledge and to include exception handling mechanisms. (The SweetDeal approach enables software agents to create, evaluate, negotiate, and execute contracts with substantial automation and modularity.)
- Enables thereby more complex contracts with behavioral provisions.
- Provides a foundation for representing and automating contractual *deals about Web Services* (and e-services more generally), so as to help search, select, and compose them.
- Gives a new point of convergence between Semantic Web and Web Services – thereby newly fleshing out the evolving concept of *Semantic Web Services*.
- Gives a conceptual approach to specifying LP/RuleML rules “on top of” DL/DAML+OIL/OWL ontologies (for the first time to our knowledge). Moreover, this is for the highly expressive SCLP case of RuleML. And this is one of the first two published descriptions and examples of combination of DAML+OIL (or OWL) with a *non-monotonic* rule KR — the other being [19] which was done independently. Our approach to rules on top of ontologies is described here conceptually and by examples, but only informally, however, in that we lack space here to give a formal semantics (or proof theory) for it.
- Combines (SC)LP/RuleML with DL/DAML+OIL (i.e., emerging Semantic Web rules with emerging Semantic Web ontologies) *for a substantial business application domain scenario/purpose* (for the first time, to our knowledge).

A prototype is running. We intend to make it publicly available in the near future.

For more discussion of conclusions, and of the larger SweetDeal effort, see the Introduction.

10. FUTURE AND RELATED WORK

One interesting research direction is to develop more and longer example scenarios and test them out by running them using SweetRules together with tools for DAML+OIL/OWL and, later, tools for reasoning specifically about process knowledge. In particular, we are investigating aspects specific to Web Services. We are focusing on relating our SweetDeal approach and its elements (rules, ontologies, process knowledge) to the Web Services area's standards (e.g., WSDL [24]), techniques (e.g., SOAP invocations [23], UDDI [25]), and exploratory application areas. A second interesting direction is how to incorporate legal aspects of contracting into our approach, including to connect to the Legal XML emerging standards effort [26].

Other interesting directions involve ontologies. One is to further develop the DAML+OIL/OWL ontology for business processes, e.g., by drawing on the Process Handbook. A second is to further develop the contract ontology. Currently, we are investigating how to formalize more deeply the relationship between a contract rulebase and a rule-based handler process.

An important aspect of ontologies, mentioned earlier, is to develop the theory of combining rules on top of ontologies, including expressive union and intersection, semantics, proof theory, algorithms, and computational complexity. Our development of this theory is in progress [27]. This will also provide a principled basis for unifying the syntax of the rules with that of the ontologies, e.g., using RDF for both.

Yet other directions for future work include tying in to agent negotiation strategies: to emerging standards for general-purpose e-business/agent communication, e.g., ebXML [20], LegalXML eContracts [34], Web Services Choreography Interface [35], and FIPA's Agent Communication Language [21]; to more general efforts on combining Semantic Web and Web Services, e.g., DAML-S and Web Service Modeling Framework (WSMF) [28]; and to efforts on ontology translation and knowledge integration for relevant tasks/domains such as financial information, e.g., ECOIN [36].

Finally, there is the challenge of how to cope with the issue of default inheritance in regard to DAML+OIL/OWL and also to the Process Handbook. In current work, we are taking an approach to default inheritance using the prioritized conflict handling capability provided by the courteous feature of SCLP.

11. ACKNOWLEDGEMENTS

Thanks to our MIT Sloan colleagues Mark Klein, Chrysanthos Dellarocas, Thomas Malone, Peyman Faratin, and John Quimby for useful discussions about the Process Handbook and representing contract exceptions there. Thanks to anonymous reviewers on a previous version for helpful comments. Partial funding support was provided by the Center for eBusiness @ MIT, and the DARPA Agent Markup Language program.
